Development and validation of an international appraisal instrument for assessing the quality of clinical practice guidelines: the AGREE project

The AGREE Collaboration

Background: International interest in clinical practice guidelines has never been greater but many published guidelines do not meet the basic quality requirements. There have been renewed calls for validated criteria to assess the quality of guidelines.

Objective: To develop and validate an international instrument for assessing the quality of the process and reporting of clinical practice guideline development.

Methods: The instrument was developed through a multi-staged process of item generation, selection and scaling, field testing, and refinement procedures. 100 guidelines selected from 11 participating countries were evaluated independently by 194 appraisers with the instrument. Following refinement the instrument was further field tested on three guidelines per country by a new set of 70 appraisers.

Results: The final version of the instrument contained 23 items grouped into six quality domains with a 4 point Likert scale to score each item (scope and purpose, stakeholder involvement, rigour of development, clarity and presentation, applicability, editorial independence). 95% of appraisers found the instrument useful for assessing guidelines. Reliability was acceptable for most domains (Cronbach’s alpha 0.64–0.88). Guidelines produced as part of an established guideline programme had significantly higher scores on editorial independence and, after publication of a national policy, had significantly higher quality scores on rigour of development (p<0.005). Guidelines with technical documentation had higher scores on that domain (p<0.0001).

Conclusions: This is the first time an appraisal instrument for clinical practice guidelines has been developed and tested internationally. The instrument is sensitive to differences in important aspects of guidelines and can be used consistently and easily by a wide range of professionals from different backgrounds. The adoption of common standards should improve the consistency and quality of the reporting of guideline development worldwide and provide a framework to encourage international comparison of clinical practice guidelines.

Clinical practice guidelines are now a common feature of clinical practice and are of interest worldwide. They are expected to facilitate more consistent, effective and efficient medical practice, and improve health outcomes. Governments, professional associations, and healthcare organisations are increasingly sponsoring the development and dissemination of clinical guidelines. There is also a growing number of guidelines developed by European or international groups.

Although the principles for the development of sound guidelines are well established, many published guidelines fall short of the basic quality criteria identified in two recent studies. Defining the quality of guidelines is not straightforward. In principle a “good” guideline is one that eventually leads to improved patient outcome. It needs to be scientifically valid, usable, and reliable. However, this evidence is rarely available. Often the best that can be expected is some information on whether the guideline producers have attempted to minimise all the biases that can occur in the complex process of creating a guideline and how well this is reported.

As the number of published guidelines proliferates, there have been calls for the establishment of internationally recognised standards to improve the development and reporting of clinical guidelines. Moreover, there is a pressing need for internationally recognised criteria that are valid, reliable, and useful for various assessment purposes in different countries, both for guideline developers and clearing houses as well as individual users of guidelines.

In response, an international group of researchers from 13 countries—the Appraisal of Guidelines, REsearch and Evaluation (AGREE) Collaboration—has developed and validated a generic instrument that can be used to appraise the quality of clinical guidelines. The AGREE instrument is designed to assess the process of guideline development and how well this process is reported. It does not assess the clinical content of the guideline nor the quality of evidence that underpins the recommendations. In this paper we report the development and validation of the AGREE instrument.

METHODS

A multi-staged approach was used that included an item generation, selection and scaling process, and field testing and refinement procedures.

Item generation, selection, and scaling
To develop the framework for the instrument, quality was defined as the confidence that the biases linked to the rigour of development, presentation, and applicability of a clinical practice guideline have been minimised and that each step of the development process is clearly reported. We considered the following five theoretical quality domains:

- scope and purpose;
- stakeholder involvement;
- rigour of development;
- clarity and presentation;

A small working group (FC, JB, RG, PL) generated an initial list of 82 items from validated appraisal instruments and relevant literature that addressed these domains. The working group examined the list for coverage, overlap and content validity, and reduced it to 34 items. The list and a user guide describing the items were pretested on two Dutch and two English guidelines and refinements were made in response to the comments received.

The refined list and user guide were then circulated to all the AGREE partners and to 15 international experts for their views on the clarity, comprehensiveness, relevance, and ease of use. In addition, the AGREE partners were asked to apply the instrument to two guidelines each. The feedback from this process led to reformulation of ambiguous items and removal of overlapping and value laden items. The result was the first draft instrument comprising 24 items grouped into the five domains identified in the development phase. We also modified the user guide to reflect changes made to the items. A 4 point Likert scale was used to score each item (1=strongly disagree, 2=disagree, 3=agree, 4=strongly agree). A 3 point scale (1=not recommend, 2=recommend with provisos or modifications, 3=strongly recommend) was used to score an overall judgement on whether the guideline ought to be recommended for use.

Field testing and refinement

The AGREE collaborators field tested the instrument following a research protocol that covered selection criteria for the guidelines, methods for recruiting appraisers, and time scales (Box 1). Each country coordinated the appraisal of at least seven guidelines. Each guideline was assessed independently by four appraisers and, where possible, each appraiser assessed two guidelines. The appraisers received a standard letter with instructions on how to complete the instrument. Most used an English version of the draft AGREE instrument. If necessary, the materials or the user guide only were translated to ensure appraisers’ understanding of the items. Feedback on the instrument, user guide, and the appraisal process was solicited with a standard letter, translated into a national language where necessary.

The field test was conducted in winter 1999–2000 with the 24-item draft instrument. For this phase, 100 guidelines from 11 countries (mode=8, range 7–22) were evaluated by 194 appraisers. The results of this field test were reviewed at an AGREE workshop in spring 2000 and the instrument and user guide were refined in response to the results. The final version of the instrument underwent further field testing in autumn 2000. In this phase a random sample of three guidelines per country from the original 100 were assessed by 70 newly recruited appraisers.

Data analysis

Mean item scores for each guideline were calculated by averaging the scores across the four appraisers. Standardised domain scores for each guideline were calculated by summing scores across the four appraisers and standardising them as a percentage of the possible maximum score a guideline could achieve. Mean item and standardised domain scores were used in the analyses unless otherwise noted below.

To guide the refinement of the instrument from the draft version to the final version, a principal components analysis was undertaken with data from the first field test. The mean item scores for each of the 100 guidelines were included in the analysis, with the eigenvalue limit set at 1 and the criteria for the minimum loading score set at 0.52.

Final instrument properties

Reliability

Two measures of reliability were conducted:

1. Using mean item scores, the Cronbach α coefficient was calculated to measure internal consistency of each domain of the final instrument.

2. Intraclass correlations (ICC) were calculated to assess the reliability within each domain. ICCs based on single appraisers’ ratings and the means of two, three, and four appraisers were calculated.

Validity

Several measures of validity were considered:

1. Face validity: appraisers’ attitudes about the instrument and user guide were collected by questionnaire and used to assess face validity.

2. Construct validity: three hypotheses were considered for tests of construct validity:

   (a) Established guideline programmes have opportunities to compose and refine guideline development methodologies, create efficiencies of process, and access committed funds. It was therefore hypothesised that guidelines originating from established programmes would have higher domain scores than those produced outside an established system. To test this hypothesis, a series of one way ANOVAs on quality scores was undertaken for each domain with type of guideline programme (established/not established) as the between subject factor.

   (b) It can be argued that guidelines supported by well documented technical information—either within the guideline itself or as part of supporting reports or publications—will have domain scores higher than those without this documentation. To test this notion, Kendall’s tau B rank correlation tests on quality scores for each domain were undertaken.

   (c) Guidelines developed as national policies should be particularly robust because of the authority conferred on them. It was therefore predicted that guidelines created on a national level should be of higher quality than regional or local ones. To test this notion a series of one way ANOVAs on quality scores was undertaken for each domain with level status (national/other guidelines) as the between subject factor.

3. Criterion validity: as there is no gold standard in this area, participants’ overall assessment scores were used as a proxy measure. Assessments of criterion validity were assessed by calculating the Kendall’s tau B rank correlation coefficients.
between the appraisers’ domains scores and the overall assessment scores.

**RESULTS**

The median time for appraising a guideline was 1.5 hours in both field studies. This included reading the guideline and completing the instrument. All appraisals were completed and returned.

**Refinement of instrument**

Principal components analysis of the draft instrument items yielded a five-factor solution that generally supported the domains of quality identified in the development phase. Table 1 shows the list of items and their loading (correlation) coefficients on each of the five domains from the rotated factor matrix.

Editorial independence appeared to load on several domains. In response, it was shifted to a sixth domain in the final version of the instrument and a new item addressing conflicts of interest was included. Two items—“The guideline is clearly structured” and “The potential problems with changes of attitude or behaviour of health care professionals in applying the guidelines have been considered”—were removed from the final version of the instrument because of

*p<0.05, **p<0.01.

Failure to establish adequate reliability in the first field test. Finally, 10 items were reworded slightly in the final version of the instrument in response to feedback received from the appraisers (see Face validity below). The refined instrument in its final form contained 23 items grouped into six domains with the 4 point Likert scale to score each item (table 1).

Final instrument properties
Reliability
Internal consistency ranged between 0.64 and 0.88 and was acceptable for most domains (table 2). The lower α coefficient found for domain 6 (editorial independence) was not surprising as this domain was composed of only two items. Table 2 also shows the intraclass correlations for each domain as a function of the number of raters. As would be expected, the number of appraisers evaluating a guideline affected reliability; increasing the number of raters resulted in substantially higher ICCs.

Validity
Face validity
Results from the first field test indicated that the appraisers found the instrument useful to assess guidelines (95%) and the user guide helpful (98%). However, almost half of the participants reported having difficulties with at least one item of the instrument (49%). The most commonly reported problem was that guidelines lacked the detailed information necessary to assign a score. After refinement of the instrument, results from the second field test showed that the percentage of appraisers reporting difficulties with at least one item in the instrument decreased to 29%.

Construct validity
Tests of the first hypothesis showed that guidelines produced as part of a guideline programme had significantly higher scores on domain 6 (editorial independence) than those published outside a programme (p<0.05). Tests of the second hypothesis showed that guidelines with technical documentation had higher scores on domain 3 (rigour of development) than those published without documentation (p<0.01). Finally, tests of the third hypothesis revealed that guidelines produced after the publication of a national policy had significantly higher quality scores on domain 3 (rigour of development) than did their counterparts (p<0.05). No other significant differences emerged on any of the other domains for any of the contrasts (table 3).

Criterion validity
Kendall’s τB rank correlation coefficients between the appraisers’ domain scores and their overall assessments were all highly significant (p<0.001), providing some evidence of criterion validity using this proxy measure. Table 4 shows the correlation matrix of the six quality domains. With one exception, the domains tended to be more highly correlated with overall judgement than with each other.

DISCUSSION
This is the first time an appraisal instrument for clinical practice guidelines has been developed and tested at an...
was not strong. It was somewhat surprising to observe that contribution of each domain to the overall quality of a guide-
that need testing empirically, and we do not know the relative
domains, each assessing key quality attributes. However, the
be kept in mind. Firstly, the factor analysis confirmed our
useful for judging the quality of guidelines.

ers found the instrument easy to apply and perceived it to be
lines with the AGREE questions and user guide. The apprais-
ment for judging the quality of guidelines before adopting them.

in important aspects of clinical practice guidelines, and

our results show that the instrument is sensitive to differ-
ences in important aspects of clinical practice guidelines, and
it can be used consistently by a wide range of professionals
from different cultural backgrounds. Health professionals,
policy makers, and consumers were all able to appraise guide-
ines in the same institution and from the same country.1,7
This study resulted in a rigorously developed set of criteria for
appraising guidelines (box 2) that can be helpful for clinical
practice in two ways: (1) to help clinicians to differentiate
between guidelines from different sources, and (2) as a
support to the development of high quality guidelines for
medical practice.

Our results show that the instrument is sensitive to differ-
ces in important aspects of clinical practice guidelines, and
it can be used consistently by a wide range of professionals
from different cultural backgrounds. Health professionals,
policy makers, and consumers were all able to appraise guide-
lines with the AGREE questions and user guide. The apprais-
ers found the instrument easy to apply and perceived it to be
useful for judging the quality of guidelines.

When interpreting the results, several considerations must be
kept in mind. Firstly, the factor analysis confirmed our
conceptual framework, lending support to the assumption
that the quality of clinical guidelines is composed of distinct
domains, each assessing key quality attributes. However, the
concept of guideline quality is still grounded in assumptions
that need testing empirically, and we do not know the relative
contribution of each domain to the overall quality of a guide-
line. Construct validity, based on three a priori hypotheses,
was not strong. It was somewhat surprising to observe that

international (as opposed to local) development and established
(as opposed to more recent) programmes supporting produc-
tion did not predict validity more strongly. The high
correlations found between the domain scores and the overall
assessment corroborated the modest criterion validity, al-
though the effect may be attenuated by the fact that the
appraisers made their global ratings after assessing the guide-
lines.

Secondly, the reliability of the domains is directly affected
by the number of appraisers assessing one guideline. Thus,
using four appraisers will yield a more reliable assessment
than using a single appraiser.19 In this study average ratings of
four raters provided the most reliable assessment and we re-
comm mend that at least four raters should be used when using
the instrument.

Finally, we were not able to demonstrate conclusively the
validity of our instrument. The instrument assesses the meth-
odological quality of a guideline and this relies heavily on how
well documented the guideline development process is.26
However, explicit reporting does not guarantee optimal
recommendations. A well reported guideline may contain
flawed recommendations and, conversely, an unsystematically
constructed one may provide sound evidence.20 Nevertheless,
the criteria we used are accepted as key determinants of valid
and effective guidelines among methodologists, and the
domains are quite clear. Validation of the instrument is a chal-
lenging task. We are currently undertaking detailed content
analysis of the appraised guidelines as part of our research
programme. This will provide a separate measure of construct
validity.

AGREE has considerable implications for research and
policy. These standards for the development and reporting of
clinical practice guidelines can be used by guideline producers
worldwide. The adoption of such standards can improve the
consistency and quality of the reporting process.25 The sharing
of standards across countries will facilitate international com-
parison of guidelines and can provide a framework for studies
aimed at understanding why guidelines for the same condition
may produce differing recommendations.22-23

As the number of clinical practice guidelines submitted
for publication increases, there is a need to ensure that they sat-
sify certain minimum requirements. AGREE can be adopted
by editors of peer reviewed journals as a framework to assess
the quality of clinical guidelines in the same way that
CONSORT is used to judge the quality of randomised controlled
trials and meta-analyses.24 25

Given the expansion of national guideline programmes,
governments and other agencies must ensure the guidelines
are of the highest quality before they endorse them or promote
their use in practice. Furthermore, as international coopera-
tion between countries grows there is a strong incentive for
policy makers to develop a concerted approach to quality
management initiatives, including clinical practice guidelines.
The AGREE instrument can enhance this process. This is
already taking place as several agencies—such as the National
Institute for Clinical Excellence (NICE) in the UK, the
National Federation of Cancer Centres (FNCLCC) in France,
The Agency for Quality in Medicine in Germany (ÄZQ), and
the Scottish Intercollegiate Guidelines Network (SIGN)—are
using AGREE in the context of their guidelines programme.
The World Health Organisation has adopted the AGREE
instrument to assess its guidelines.

In conclusion, the AGREE collaboration has developed an
instrument for guideline appraisal using a rigorous method-
ology. The instrument has been applied to different clinical
practice guidelines in 11 countries by a large number of
appraisers from a variety of backgrounds. We recommend that
guideline producers use this instrument while planning their
programmes, and potential guideline users use it to evaluate
the quality of guidelines before adopting them.

The AGREE instrument is available on the AGREE website
(www.agreecollaboration.org).

Box 2 Criteria of high quality clinical practice guidelines

1. Scope and purpose

Contain a specific statement about the overall objective(s),
clinical questions, and describes the target population.

2. Stakeholder involvement

Provide information about the composition, discipline, and
relevant expertise of the guideline development group and
involve patients in their development. They also clearly
define the target users and have been piloted prior to pub-
llication.

3. Rigour of development

Provide detailed information on the search strategy, the
inclusion and exclusion criteria for selecting the evidence,
and the methods used to formulate the recommendations.
The recommendations are explicitly linked to the
supporting evidence and there is a discussion of the health
benefits, side effects, and risks. They have been externally
reviewed before publication and provide detailed information
about the procedure for updating the guideline.

4. Clarity and presentation

Contain specific recommendations on appropriate patient
care and consider different possible options. The key rec-
commendations are easily found. A summary document and
patients’ leaflets are provided.

5. Applicability

Discuss the organisational changes and cost implications
of applying the recommendations and present review criteria
for monitoring the use of the guidelines.

6. Editorial independence

Include an explicit statement that the views or interests of
the funding body have not influenced the final recommenda-
tions. Members of the guideline group have declared
possible conflicts of interest.
Key messages

The problem
Clinical practice guidelines are used increasingly by government agencies and professional organisations around the world to improve patient care, but many published guidelines do not meet the basic quality criteria. There is a pressing need for internationally recognised criteria to assess guidelines that are valid and reliable.

What this study adds
- An international collaboration, the AGREE Collaboration, has developed an instrument for assessing the process of guideline development worldwide.
- It was not possible to confirm the validity of the instrument.
- The instrument provides common standards to improve the quality process and reporting of guideline development worldwide.
- These standards can be used for the planning, execution, and monitoring of guideline programmes and for comparing guidelines internationally.

ACKNOWLEDGEMENTS
The authors would like to thank the 264 appraisers from the 11 countries who participated in the study and the following colleagues for their valuable comments on the first draft of the instrument: Richard Baker, Martin Eccles, Roeland Geijer, Trisha Greenhalgh, Allen Hutchinson, Nick Hicks, Chris Silagy, Siep Thomas, Richard Thomson, Michel Wensing and Steven Woolf.

Writing group: Françoise Cluzeau (FC), St George’s Hospital Medical School, London, UK; Jako Burgers (JB), University of Nijmegen; The Netherlands; Michael Eccles, National Institute for Clinical Excellence, UK; Claire Hunt (CH), Institute of Psychiatry, London, UK; Jeremy Grimshaw (JG), Health Services Research Unit, University of Aberdeen, UK; Albert Jovell, Fundacio Biblioteca Hospital Européen Georges Pompidou, Paris, France; Béatrice Fervers, Spain; Anne Bataillard, Fédération Nationale des Centres de Lutte Contre Field MJ, Field M, Lohr KN, eds. Guidelines for clinical practice. From development to use. Institute of Medicine. Washington DC: National Academy Press, 1992.
