Effectiveness Bulletin

Mental health promotion in high risk groups

Amanda J Sowden, Sylvia Tilford, Faith Delaney, Michelle Vogels, Simon Gilbody, Trevor A Sheldon

An important component of an effective coordinated strategy for the promotion of mental health and the primary prevention of mental distress is the identification of and effective intervention with groups of people who are at high risk of experiencing mental health problems. A large body of epidemiological research has identified several characteristics of people who are at high risk (box).1-8

This paper summarises the findings of a recent issue of the Effective Health Care bulletin.9 This reviewed the results of randomised controlled trials of interventions aimed at one of the high risk groups shown in the box, in people who were not diagnosed as mentally ill, or were not in receipt of mental health services, and which reported either mental health and wellbeing outcomes or measures of mental distress. This summary is based on elements of two recent systematic reviews of mental health promotion10-12 and other relevant reviews. These were updated by systematic searches from 1995 to April 1997 with the same search strategy as that used by Tilford et al.13 Few reliable economic evaluations have been carried out in this area.14 This review does not cover other vulnerable groups such as those with physical illness or disability, children living with adults who have mental health problems, or those who have been abused. It also excludes a discussion of psychological debriefing for people who have experienced major trauma, as there is little reliable evidence that debriefing interventions improve mental health outcomes.14 15

Children
LIVING IN POVERTY
Children in socially disadvantaged communities are at higher risk of experiencing mental health problems in childhood and later life. Evaluations of social interventions aimed at improving the health and social outcomes of these children have been summarised elsewhere.16 High quality preschool and nursery education such as the Head Start and the High/Scope (Perry preschool) projects have shown improvements in self esteem, motivation, and social behaviour and other educational and social outcomes.17 Social support visits to new parents to provide them with strategies for tackling child care and child rearing issues have been shown to be effective unless deficits in parental skills are accompanied by a combination of health and socioeconomic problems. A trial of support by mature lay mothers showed improvements in maternal mental health and child care.18

BEHAVIOURAL PROBLEMS (TABLE 1)
When childhood behaviours such as mood changes and expressed aggression are sufficient to cause distress to the child or others it is sometimes considered to constitute disordered behaviour. Childhood mental distress is strongly predictive of adverse mental health and social outcomes later in life and so prevention may bring long term psychiatric, social, and economic benefits.3 19 Various studies have explored the effectiveness of training parents to develop the skills necessary to deal effectively with childhood

Groups at high risk of mental health problems considered in the bulletin

behavioural problems. Interventions involving parental role playing, behavioural management, and play skills reduced attention deficit and hyperactivity symptoms as rated by teachers and parents. Similarly, a trial in Ireland found that parent training resulted in improved child behaviour, psychological symptoms, and increased parental self confidence. A two year programme of family management training aimed at parents and social skills training for seven year old boys assessed as disruptive by teachers was highly effective at reducing various measures of behavioural and adjustment problems measured after a further three years of follow up. Individual home based training of parents in these social learning techniques may be cheaper than and as effective as office based individual and group training. This suggests that parent training programmes—for example, self administered videotape training—should be effective, improving parent-child interactions and behaviours in children referred for treatment for conduct disorders can also be useful in preventive settings.

Two trials examined the effect of school based social skills training on socially rejected children. Both showed improvements in social skills and less social isolation.

Neatly, that school attenders with low self esteem benefited from a cognitive behavioural

intervention delivered by an interactive personal computer program in a school setting over two days.26 However, this has yet to be evaluated as a health intervention. Ethnic minority teenagers with severe behaviour problems in the United States showed modest improvements in self concept and short term reductions in anxiety after an intervention based on social learning theory in which they were exposed to positive adult role models of the same ethnic group.27

PARENTAL DIVORCE OR BEREAVEMENT (TABLE 2) Children who experience serious adverse life events such as parental separation or bereavement may experience behavioural and emotional problems.3 School based programmes for children of divorcing parents have been shown to increase mental health. The children of divorce intervention programme (CODIP) used weekly school based sessions, to communicate feelings, and provide emotional support and the skills needed to resolve interpersonal problems. Ten year olds showed greater gains in adjustment and lower anxiety than controls,30 a finding also found in less rigorous evaluations in younger children and ethnic minorities31 32 but no long term follow up has been reported. A more labour intensive intervention in 7-10 year olds showed improved skills in children's adjustment to their circumstances, so reducing anxiety and improving their ability to deal with emotional conflict after one year.33

Workshops for children who have experienced the death of a parent that explored issues of grief and loss and its relation to family dynamics reported improved relations between

Mental health promotion in high risk groups

UNEMPLOYMENT (TABLE 4)
An evaluation of a United States programme (JOBS) aimed at improving job search and problem solving skills and "inoculating" the recently unemployed against set backs, showed better mental health, motivation, and employment outcomes which were sustained over a 2.5 year follow up. A subsequent large randomised field study (JOBS II) confirmed that the benefit was confined to people with fewer depressive symptoms, less financial strain, and low assertiveness, as identified by a screening instrument. A recent United Kingdom trial has shown that group cognitive behavioural training can increase general mental health, possibly by increasing re-employment in long term unemployed professionals.

DEPRESSION IN PREGNANCY (TABLE 5)
Postnatal depression affects between 10% and 15% of mothers and may lead to chronic mental health problems in a considerable proportion of women. This can also adversely affect the child. Simple self completion screening instruments have been developed to identify high risk mothers. However, these may not be sufficiently accurate for routine use.

Interventions specifically designed to prevent postnatal depression have shown contradictory results.

Trials of home based social support given to high risk (socially disadvantaged) pregnant women by midwives or lay mothers supported by nurse professionals strongly suggest that various forms of home support or home visiting during pregnancy can improve mental health.

<td>Participants: mainly male voluntary AIDS caregivers with high level of tertiary education in Australia; I: counselling by 3 homosexual experienced counsellors.</td>
<td>I group had immediately lower levels of anxiety than C (p&lt;0.05); this difference wore off by 3 months as the anxiety levels in the C group dropped (p&gt;0.1) Attrition: I=39%; C=42% High rate of attrition.</td>
</tr>
</tbody>
</table>
wellbeing of mothers and their children.\textsuperscript{16} 52 53 Trials also indicate that continuous support for women during labour (by friends or volunteer labour companions) can reduce postnatal depression and raise self esteem.\textsuperscript{54}

Several trials have also evaluated interventions specifically designed to reduce postnatal depression.\textsuperscript{44} 49 50 The results are contradictory. Women who experience a miscarriage (around 20\% mainly in the first three months) or a perinatal death are also at increased risk of psychological morbidity especially in the first few months. None of the three trials examining various forms of counselling or psychological debriefing, however, showed a sustained effect.\textsuperscript{45-57}

\textbf{BEREAVEMENT (TABLE 6)}

Several programmes aimed at reducing mental health problems in recently bereaved spouses have been evaluated in randomised controlled trials. The family bereavement programme already mentioned\textsuperscript{44} showed positive effects on children and their parents. Running grief workshops (a self help “widow to widow” programme), in which recently widowed women received support from another widow and attended small group meetings, showed accelerated achievement of landmark stages—such as starting new relations and activities. However, there were several weaknesses in the methods.\textsuperscript{58} In contrast, bereavement counselling showed no effect on quality of life, satisfaction, or frustration levels of key people of deceased cancer patients.\textsuperscript{59} A small trial failed to show any difference in depression, after receiving different models of nurse led group psychotherapy, in spouses of people who had committed suicide.\textsuperscript{60}

\textbf{LONG TERM CARERS OF HIGHLY DEPENDENT PEOPLE (TABLE 7)}

There are many publications which have evaluated ways of improving the psychological health of people who care for others who are highly dependent either because of age or physical or mental ill health. A meta-analysis looked at 20 controlled evaluations of interventions in which distress of caregivers was a principal outcome.\textsuperscript{61} A quantitative review of 15 studies (over half of which were randomised controlled trials) suggested that only two types of interventions have been shown to have any effect: individual psychosocial interventions and receipt of respite care. Group psychosocial interventions showed less effect, a finding confirmed in studies that directly compared individual and group interventions.\textsuperscript{62}

Several other experimental evaluations have been reported since this meta-analysis. Two trials show that interventions—such as carers, group sessions combined with either training in assertiveness and coping skills,\textsuperscript{63} or counselling,\textsuperscript{64} can reduce psychological morbidity in those caring for elderly people with Alzheimer’s disease, at least in the short term. Also, a psychoeducational programme was found to increase the coping ability of adult children caring for aging parents.\textsuperscript{65}

A group intervention aimed at spouses of frail elderly veterans also resulted in short term improvements in coping and reduced stress.\textsuperscript{66} Support with case management and respite care was shown to reduce depression and anxiety in parents of children with handicapping conditions.\textsuperscript{67}

Randomised controlled trials of counselling by itself showed no sustained effect on improving carers’ mental health or reducing strain in the following areas: community based caregivers of patients with AIDS,\textsuperscript{68} family caregivers of patients admitted for schizophrenia,\textsuperscript{69} or spouses and patients undergoing treatment for cancer.\textsuperscript{70}

\textbf{Conclusions}

Individual people and groups who are at increased risk of developing mental health problems can be identified and various preventive interventions have been shown to be effective. Children showing behavioural disorders may benefit from a range of interventions including training to improve parenting skills and school based training in social skills. A variety of socially based cognitive and behavioural interventions can be used effectively in children who have had adverse life events such as parental separation, divorce, and bereavement. Specific interventions can help adults adjust to adverse life events such as job loss, bereavement, and divorce. Some psychosocial interventions aimed at promoting support and coping skills, along with respite care, can help to reduce the high levels of strain in carers. There is little evidence that generic counselling, provided by itself, is particularly effective.
