Objective: To describe the drugs and types of medicine management problems most frequently associated with preventable drug related admissions to an acute medical admissions unit.

Design: Observation study.

Setting: Medical admissions unit in a teaching hospital in Nottingham, UK.

Participants: 4093 patients seen by pharmacists on the medical admissions unit between 1 January and 30 June 2001.

Main outcome measures: Proportion of admissions that were drug related and preventable, classification of the underlying causes of preventable drug related admissions, and identification of drugs most commonly associated with preventable drug related admissions.

Results: Of the admissions seen by pharmacists, 265 (6.5%) were judged to be drug related and 178 (67%) of these were judged to be preventable. Preventable admissions were mainly due to problems with prescribing (63 cases (35%)), monitoring (46 cases (26%)), and adherence to medication (53 cases (30%)). The drugs most commonly implicated were NSAIDs, antiplatelets, antiepileptics, hypoglycaemics, diuretics, inhaled corticosteroids, cardiac glycosides, and beta-blockers.

Conclusions: Potentially preventable drug related morbidity was associated with 4.3% of admissions to a medical admissions unit. In 91% of cases these admissions were related to problems with either prescribing, monitoring, or adherence.

Recent reports in the USA¹ and the UK² highlight the problem of drug related morbidity and the need to find ways to prevent medical errors. These reports suggest that preventable drug related admissions require particular attention and, in 2002, two systematic reviews were published on this topic.^{3,4} Winterstein *et al*³ identified 15 studies of preventable drug related hospital admissions and found a median of 7.1% of admissions to be drug related, and 59% of these to be preventable. Beijer *et al*⁴ reviewed 68 studies, 12 of which looked at preventable admissions. This review highlighted some of the limitations of previous research and emphasised the need for further studies looking at the preventability of drug related admissions and documentation of the drugs responsible for these admissions. This sort of information is needed if we are to develop effective strategies to prevent drug related admissions. In addition, it is important to identify some of the underlying causes of preventable admissions.

We have addressed some of these issues by conducting a large study of drug related morbidity detected by pharmacists on a medical admissions unit in the UK. We have defined drug related morbidity as adverse drug reactions,⁵ failure to optimise treatment, unintentional overdose, and adherence problems. Admissions associated with intentional overdoses and drugs of abuse were excluded.

The objectives of our study were to:

- estimate the proportion of admissions to an acute medical admissions unit that were associated with drug related morbidity and the proportion of these admissions that were potentially preventable;
- identify the drugs associated with the preventable drug related admissions;
- classify preventable drug related admissions by the underlying causes—for example, prescribing problems, monitoring problems, adherence problems and supply problems.

METHODS

Selection of participants

The local research ethics committee approved the study. All patients admitted to the medical admissions unit (box 1) and seen by a pharmacist between 1 January and 30 June 2001 were included in the study. The pharmacists saw patients as part of their routine work Mondays to Fridays. They recorded details of all patients seen and reported patients with any suspected drug related morbidity to the principal investigator

Box 1 Description of the Medical Admissions Unit at Queens Medical Centre, Nottingham

The medical admissions unit at Queens Medical Centre (QMC), Nottingham is a 30 bed unit which receives acute medical admissions from general practitioners and the A&E department. A small number of admissions come from other hospitals or wards within the QMC (these were not included in the study). The ward is covered Monday to Friday by three admissions ward pharmacists (all have a clinical diploma) between 07.00 and 19.00 hours. The pharmacists are responsible for checking the medication histories of patients admitted (by reviewing patients' own medication, questioning patients, contacting general practice surgeries and nursing homes, etc), as well as supplying medication and ensuring the safety of the prescribing on the unit. Part of this role inevitably involves identifying drug related morbidity.

There are two consultant-led multidisciplinary ward rounds each day (morning and evening) which are attended by one of the admissions unit pharmacists.

Overnight and at weekends the admissions unit is covered by a limited pharmacy service.

Figure 1 Flow of patients through the study.

Box 2 Details included in the case summaries

- Unique identifier
- Patient's age
- Sex
- Date of admission
- Date of discharge
- Presenting complaint
- Medication history (before admission to hospital)
- Medication on discharge
- Events leading up to the admission
- Summary of hospital treatment
- Test results
- Diagnosis made by the physicians caring for the patient in hospital

(RH). Similar methods have been used successfully in at least five previous studies.⁶⁻¹⁰

The principal investigator assessed possible cases using a combination of:

- medical note review (throughout the admission and on discharge);
- contact with general practitioners, where necessary, to obtain medication histories, test results, and information regarding the management of patients in primary care;
- interviewing patients, where possible, about the type and duration of symptoms and medication use, using an interview schedule. Those not interviewed included patients discharged home before being seen by the principal investigator, patients too unwell to be interviewed, and patients unable to speak English.

Following assessment by the principal investigator, some cases were excluded from further review (fig 1). These included cases where further investigation suggested that drug related morbidity was unlikely—for example, a low probability VQ scan in a case of suspected pulmonary embolism in a woman taking a combined oral contraceptive. In order to ensure that some patients were included in the study who had been admitted at weekends, the principal investigator identified patients with potential drug related morbidity through medical note review and patient interview on alternate weekends (fig 1).

Classification of potential drug related admissions

Following discharge from hospital, the principal investigator prepared detailed case summaries on patients with suspected

Box 3 Criteria used to review possible drug related admissions cases

Amended Hallas criteria for causality

- (1) Known adverse drug reaction, toxic reaction, response to omission of treatment or inadequate treatment.
 - (2) Reasonable temporal relationship between commencement or cessation/omission of treatment and onset of problem.
 - (3) Risk of further problems likely to be reduced by dose reduction or increase, discontinuation, closer monitoring or commencement of treatment.
 - (4) Not explained by any other known condition of predisposition to the patient, or this condition/predisposition is likely to be exacerbated by the presence/absence of the drug.
 - (5) For drug toxicity:
 - symptoms re-appeared upon re-exposure;
 - laboratory tests showed toxic drug levels or drug induced metabolic disturbances that explained the symptom;
 - symptoms resolved on dose reduction or discontinuation of the drug.
- For drug omission:
- symptoms resolved upon re-introduction of the drug or dose increase.

If 5 criteria fulfilled then **definite**.

If 4 criteria fulfilled then **probable**.

If 3 criteria fulfilled then **possible**.

If 2 or less criteria fulfilled then either, not drug related or unevaluable

Hepler criteria for preventability

- (1) Drug related morbidity (DRM) preceded by a recognisable drug therapy problem (DRP).
- (2) Given the DRP, the DRM would have been reasonably foreseeable.
- (3) The cause of DRM would have been identifiable with reasonable probability (Hallas criteria probable or definite for causality).
- (4) The cause of the DRM could have been reasonably controllable within the context and objectives of treatment.

All four criteria must be fulfilled to confirm preventability.

Contribution of drug related problem to hospital admission

Score = 3 (dominant): the suspected symptoms were the main reason for admission and no other symptoms contributed significantly.

Score = 2 (partly contributing): the suspected symptoms played a substantial role in admission, but other factors also contributed significantly.

Score = 1 (less important): the suspected symptoms played a minor or uncertain role, and the patient would probably have been admitted without them

Score = 0 (not contributing): other symptoms/circumstances were the reason for hospitalisation.

Hepler definitions for classification of drug related admissions

Score = 1: inappropriate prescribing.

Score = 2: inappropriate delivery (unavailable when needed, inappropriate formulation, failure to administer, dispensing error).

Score = 3: inappropriate behaviour by the patient (non-compliance).

Score = 4: patient idiosyncrasy (response to drug, mistake, or accident).

Score = 5: inappropriate monitoring.

Score = 6*: potentially preventable with interventions which are not standard care at present.

*Category 6 is additional to the original Hepler classification

Table 1 Primary diagnoses of patients admitted to the medical admissions unit where there was a statistically significant difference between the numbers of patients seen and not seen by a pharmacist.

Primary diagnoses classified by ICD-10 chapter heading	Patients seen by pharmacist (n=3799)	All patients admitted (n=7962)	p value*
Certain infectious and parasitic diseases	101 (2.7)	172 (2.2)	0.003
Diseases of the nervous system	153 (4.0)	283 (3.6)	0.029
Mental and behavioural disorders	84 (2.2)	151 (1.9)	0.049
Diseases of the respiratory system	702 (18.5)	1305 (16.4)	<0.001
Diseases of the skin and subcutaneous tissue	51 (1.3)	163 (2.0)	<0.001
Diseases of the musculoskeletal system and connective tissue	106 (2.8)	410 (5.1)	<0.001

Values are no (%).

*Based on χ^2 tests (1 degree of freedom).**Table 2** Reviewer agreement in scoring case summaries calculated using kappa and intraclass correlation coefficients

	Kappa for RH*TA	Kappa for RH*PH	Kappa for TA*PH	Intraclass correlation coefficient (95% CI)
Causality	0.81	0.81	0.77	0.88 (0.86 to 0.90)
Preventability	0.77	0.77	0.69	0.74 (0.70 to 0.78)
Contribution to admission	0.74	0.87	0.76	0.80 (0.78 to 0.83)
Cause of suboptimal outcome	0.78	0.71	0.67	0.75 (0.71 to 0.78)

drug related morbidity (box 2). These summaries provided reviewers with information on temporal relationships between medications and symptoms, the nature of patients' symptoms, medication changes resulting from the admission, and the diagnoses made by physicians caring for the patients. The case summaries were independently scored by a hospital physician (PH), an academic general practitioner with a special interest in prescribing (AA), and a clinical pharmacist (RH). Each reviewer scored the cases using explicit criteria for causality,¹¹ preventability,¹² contribution to the admission,¹¹ and classification of the underlying cause of the drug related morbidity¹² (box 3). All the criteria were validated in pilot study work where 46 possible cases of drug related morbidity were reviewed to ensure the criteria were reliable and gave reasonable agreement between the reviewers. After scoring the cases the reviewers met up and, in keeping with standard practice in this field,³ a majority decision was used to classify the cases where there was disagreement on any of the review criteria.

Admissions were classified as drug related if two or more reviewers scored 4 or 5 using the amended Hallas criteria and judged the drug to have made a dominant or partial contribution to the admission. Admissions were classified as potentially preventable if the above criteria were fulfilled and two or more reviewers scored 4 using the Hepler criteria for preventability.

Recording of data

For all admissions to the medical admissions unit age, sex, and date of admission were recorded on an ACCESS 97 database. The hospital routinely records details of primary diagnoses of patients admitted, classified according to the International Classification of Diseases and Related Health Problems, 10th revision.¹³ These data were available for 7962 (91%) of the admissions in our study and were imported from the hospital database into the study database.

To identify the patients seen by a pharmacist, a record was kept on the database. Data obtained from patient interviews, medical record reviews, and GP contacts were also recorded on the database and were used to generate case summaries for

the reviewers. The judgements made by individual reviewers and the final classifications for each case were double entered onto the database. In addition, details of the drugs that were thought to have contributed to the admissions were recorded and were grouped by British National Formulary codes.¹⁴

Analysis of data

Data were exported to SPSS version 10.0 for statistical analysis. To assess differences between the groups of patients seen and not seen by a pharmacist, patient characteristics were compared using an independent *t* test for age on admission and χ^2 tests for sex, day of admission, and primary diagnosis (available for 7962 (91%) of all patients admitted). To assess inter-reviewer reliability, case review scores were compared using Cohen's kappa and intraclass correlation coefficients (moderate to substantial agreement is indicated by kappa 0.41–0.80).¹⁵ The proportion of patients considered to have a drug related admission was calculated as the percentage of patients seen by a pharmacist who were classified as having definite or probable drug related morbidity that had made a dominant or partial contribution to the admission. We also calculated the proportion of drug related admissions that were considered potentially preventable. The proportion of patients considered to have a potentially preventable drug related admission was calculated as the percentage of patients seen by a pharmacist who were judged to have a preventable drug related admission.

RESULTS

Patient characteristics

The flow of patients through the study is shown in box 2. Of the 8781 patients admitted to the medical admissions unit, 4093 (47%) were seen by a pharmacist. The mean (SD) age of patients seen was 62.6 (20.7) years and the mean (SD) age of patients not seen by a pharmacist was 62.0 (20.6) years. Of the patients seen by a pharmacist 2002 (49%) were female and 2091 (51%) were male, and of the patients not seen by a pharmacist 2399 (51%) were female and 2289 (49%) were male.

Comparing patients who were either seen or not seen by a pharmacist, there were no significant differences in age

Table 3 Drug classes most frequently associated with preventable drug related admission due to prescribing problems

British National Formulary class	Adverse drug event	Prescribing problem	Number of cases
Non-steroidal anti-inflammatory drugs	Gastrointestinal toxicity	Prescription in patients with two or more risk factors without gastrointestinal prophylaxis*	21
	Renal tubular necrosis	Concurrent prescription of two full dose non-steroidal anti-inflammatory drugs without monitoring renal function	1
		Subtotal	22
Antiplatelet drugs	Gastrointestinal toxicity	Prescription in patients with two or more risk factors without gastrointestinal prophylaxis*	13
	Thrombotic event	Failure to prescribe in patients needing secondary prevention	4
		Subtotal	17
Beta-adrenoceptor blocking drugs	Congestive cardiac failure	Prescription of standard dose beta-blocker in patient with known congestive cardiac failure	2
		Co-prescription of atenolol with verapamil*	1
		Sudden cessation	1
	Tachycardia	Cessation without prescription of alternative	1
	Bleeding oesophageal varices	Failure to maximise anti-anginal therapy despite ongoing symptoms over a period of time*	2
	Chest pain		2
Antiepileptics	Fitting	Subtotal	7
		Subtherapeutic prescription	4
		Inappropriate cessation	2

*If a drug related admission involves more than one causative drug it may be recorded more than once in the table.

†Further details on "other" drug categories are available on the QSHC website (www.qshc.com/supplemental).

($p=0.168$), a weakly significant difference in sex (χ^2 24.7, df 1, $p=0.031$), and a marked difference in terms of day of admission (χ^2 568, df 1, $p<0.001$; 3070 (75%) of the patients seen by a pharmacist were admitted Monday to Thursday). Comparison of primary diagnoses indicated that those with infections, nervous system diseases, mental disorders, and respiratory diseases were over-represented in the study, and those with skin and musculoskeletal problems were under-represented (table 1).¹³

Inter-reviewer reliability

Kappa and intraclass correlation coefficients showed good to excellent agreement between the reviewers (table 2).

Proportion of admissions considered drug related

Drug related morbidity was judged to be the cause of 265 (6.5%) of the admissions seen by a pharmacist, and 178 (67%) of these were judged to be potentially preventable. The main underlying causes of preventable drug related admissions were prescribing problems ($n=63$ (35%)), monitoring problems ($n=46$ (26%)), and adherence problems ($n=53$ (30%)). Problems with administration of medication were infrequent ($n=9$ (5%)). Aspirin associated gastrointestinal bleeds were classified as "potentially preventable with interventions which are not standard care at present" ($n=7$ (4%)).

The drugs most commonly associated with preventable drug related admissions can be seen in tables 3, 4, and 5. These account for 105 (60%) of the preventable drug related admissions (details of all drugs associated with the preventable admissions are available on the QSHC website at www.qshc.com/supplemental).

DISCUSSION

In this large observational study we found that 6.5% of admissions screened by pharmacists on a medical admissions unit were judged to be drug related and 67% of these were considered preventable. The drugs most commonly associated with potentially preventable drug related admissions were NSAIDs, low dose aspirin, beta-blockers, antiepileptics, diuretics, sulphonylureas, digoxin, inhaled corticosteroids, nitrates, and insulin. These admissions were mainly attributed to problems with prescribing, monitoring, and patient adherence.

In order to minimise the risk of misclassifying cases, we used a methodology which compares well with the most rigorous studies previously reported.^{3, 8, 16, 17} We used explicit criteria to guide the assessment of cases and a three member panel of reviewers to independently classify each case. Despite the varied backgrounds of the reviewers, kappa and intraclass correlation coefficients showed good to excellent levels of agreement. Only those admissions where the drug related morbidity was judged to be the dominant cause, or partially contributing, to the admission were included as drug related admissions. Also, when we classified drug related admissions as preventable, it was our view that the problems identified were predictable and controllable in terms of the treatment (Box 4). Nevertheless, our results could be questioned in terms of the extent to which they reflect the true preventability of the observed outcomes. For example, a recent study of hospital deaths that were attributed to medical error¹⁸ suggested that in many cases the error made relatively little difference to expected fatal outcomes in seriously ill patients. While these results are not directly comparable to our study, we recognise that some of the patients in our study were at very high risk of hospital admission regardless of any preventable medication related adverse event.

In our study we reviewed only those patients seen by a pharmacist on the admissions unit. This means that our estimates of the proportion of admissions that were drug related and preventable need to be treated with some caution. The patients we studied were not fully representative of all patients admitted. However, the differences between the groups seen and not seen by a pharmacist were relatively small and, had we studied all the admissions, it is unlikely that the results would have been substantially different. In addition, our findings were similar to median figures from a recent systematic review.³

In recent years there have been calls for researchers to move beyond simply reporting preventable adverse events to finding ways of improving patient safety through avoidance of these events.^{1, 2} It has been suggested that an approach focusing on systems failures is likely to be most effective.^{1, 2, 19} The key to starting this process is to find out which types of problem are most important.²⁰

Almost 60% of the preventable drug related admissions that we found are shown in tables 3–5. These data describe the drugs most commonly associated with admissions. We have recently completed a systematic review of interventions aimed

Table 4 Drug classes most frequently associated with preventable drug related admissions due to monitoring problems

British National Formulary class	Adverse drug event	Problem	Number of cases
Loop diuretics	Overdiuresis causing dehydration ± renal failure ± electrolyte imbalance	Failure to monitor fluid balance, renal function, electrolytes etc*	7
	Congestive cardiac failure	Failure to monitor following cessation of angiotensin converting enzyme inhibitor and diuretics*	1
	Dizziness	Unnecessary polypharmacy*	1
	Hyponatraemia	Failure to check electrolytes	1
		Subtotal	10
Potassium sparing diuretics	Overdiuresis causing dehydration ± renal failure ± electrolyte imbalance	Failure to monitor fluid balance, renal function, electrolytes etc*	5
	Hyponatraemia		1
	Hyperkalaemia		1
	Dizziness	Unnecessary polypharmacy*	1
		Subtotal	8
Sulphonylureas	Hypoglycaemia	Failure to monitor blood sugar and renal function	5
	Hyperglycaemia	Failure to monitor blood sugar	3
		Subtotal	8
Cardiac glycosides	Digoxin toxicity	Failure to monitor renal function and/or digoxin levels at least annually.	4
	Fast atrial fibrillation	Failure to ensure that digoxin levels were therapeutic	1
	Dizziness	Unnecessary polypharmacy*	1
		Subtotal	6
Thiazide and related diuretics	Overdiuresis causing dehydration ± renal failure ± electrolyte imbalance	Failure to monitor fluid balance, renal function, electrolytes etc.*	4
	Hypotension ± hyponatraemia		2
		Subtotal	6

at reducing medication related morbidity in primary care.²¹ Combining evidence from this review with results from the study presented here means that we are able to suggest the types of interventions that may be most successful in reducing the incidence of preventable drug related admissions.

In terms of prescribing related problems, our study suggests that it may be worth focusing on preventing morbidity associated with NSAIDs and antiplatelet drugs. We know that patients with two or more risk factors for gastrointestinal bleeds are at high risk,²² and that various interventions can reduce the risks of these drugs.^{23–25} For example, co-prescription with ulcer healing drugs can reduce the risk of gastrointestinal bleeds²⁴ and educational interventions have been shown to improve the safety of GP prescribing.^{23, 25} Indeed, in a large Australian study an educational intervention focusing on NSAIDs reduced by 70% the rate of hospital admissions for upper gastrointestinal ulceration, bleeding and perforation.²⁵

In terms of monitoring, some of the best evidence for improvements in primary care relate to the monitoring of warfarin.^{26–30} The results of these studies may not be applicable

to other drugs, but they suggest that nurse led monitoring clinics,²⁸ computerised decision support systems,^{27, 28} patient education and involvement,²⁶ and patient self-management^{29, 30} may help to improve control through improved monitoring. In our systematic review²¹ we did not find many other studies that looked at medication monitoring in primary care, and we believe that there is a need for further research in this area.

In terms of patient adherence, a number of studies have shown that improved education^{31, 32} and approaches that provide greater involvement of patients in decision making^{31, 33} improve patient adherence and may reduce drug related admissions. However, few studies have attempted to show clinical benefits.³⁴ Our study suggests that priority should be given to patients taking the drugs listed in table 5.

Many of the problems identified in this study arise from medicines management in primary care, but it should be recognised that drug related admissions are relatively rare from the primary care perspective.³⁵ For example, while NSAIDs were responsible for 12.4% of potentially preventable admissions in

Table 5 Drug classes most frequently associated with preventable drug related admissions due to adherence problems.

British National Formulary class	Adverse drug event	Problem	Number of cases
Loop diuretics	Congestive cardiac failure	Not taking medication*	8

Key messages

- Drug related morbidity was responsible for 6.5% of admissions screened by a pharmacist and 69% were considered preventable.
- The drugs most commonly associated with the preventable drug related admissions were NSAIDs, antiplatelets, antiepileptics, hypoglycaemics, diuretics, inhaled corticosteroids, cardiac glycosides and beta-blockers.
- The majority of preventable drug related admissions were caused by problems with prescribing (35%), monitoring (26%), or adherence (30%).

our study, a German study estimated that NSAIDs were associated with just 5.5 hospital admissions per 10 000 patients treated with these drugs in primary care.³⁵ This may have important implications for encouraging general practitioners and health service managers that drug related admissions are important enough to justify potentially significant changes in medicines management. The types of changes outlined above could mean increased costs associated with gastroprotection for patients taking NSAIDs, more frequent monitoring for patients taking certain drugs (table 4), and more time spent educating patients and involving them in decision making. Nevertheless, these changes might improve safety for patients and protect healthcare professionals from litigation.

ACKNOWLEDGEMENTS

The authors thank Chris Love for providing the original idea for this study and for identifying the patients; Judy Cantrill and Caroline Morris, Almut Winterstein and Doug Hepler for advice on study design; Simone Brackenborough, Gail Marlow and Louise Brown for identifying the patients; Sarah Rodgers and James Turton for their help with the database; Karen Neil for helping to develop the review criteria; Michael Dewey and Simon Royal for statistical advice; Barry Fuertado from medical records for finding patient records after discharge; IM&T at University Hospital, Nottingham for providing admissions data; and general practitioners, practice staff and patients for their contributions.
