following criterion: 8% complete audit, 7% full audit, 31% partial audit, 13% potential audit, 15% planned audit, and 22% planning audit. At that time 4% were performing no audits, but this has subsequently been reduced to 0%.

Our two new categories are compatible with the system described by Derry et al and we hope they will prove useful to others. We agree that the usefulness of this systematic coding system will be to provide information on the progress of audit in the county and to identify those practices in need of help in pursuing their audits. We use the coding method to help us to focus our activities more effectively in facilitating the development of medical audit in Wiltshire and not in a point scoring or punitive fashion.

BOOK REVIEWS

As the NHS takes its first faltering footsteps into the new era the need for common outcome measures has become clear. Nowhere is the need more acute than in rehabilitation and disability medicine. Evaluation is urgently needed, both to identify efficacious intervention and to convince potential purchasers of its cost effectiveness. Whether for clinical use, research, audit, marketing, or any other reason, measurement is mandatory.

Not that there has been any shortage of attempts at measurement. On the contrary. Nearly every self respecting rehabilitation department in the country has developed its own scale for this or that — Frenchy, Northwich Park, Nottingham, Oswestry, Rivermead, to name but a few (and only on this side of the Atlantic). There are several scales, with different types of impairment (motor sensory, cognitive, and emotional); scales for the different levels in the World Health Organisation model of illness (impairment, disability, handicap); and scales which address the impact of disease on the patients and on those around them, scales which are disease-specific, and scales which are more general. To use a musical metaphor, some scales are almost chromatic in their compactness and attention to detail, while others give an allegro-like span of the subject. Knowing which use to can be the biggest problem of all.

Derek Wade's new book is an answer to our prayers. Not only does it act as a comprehensive guide to the common used assessments but it also gives specific advice on the choice and use of different measures. Many will be familiar with the difficulties, having read a research article, of discovering which outcome measure is used. The original scale turns out to have been published in a journal or book which is not readily available and proves, what does arrive, to be in Swedish. Validation, if undertaken at all, has usually been published in a subsequent issue, etc. The fourth section of this heavy sent book gives full details of over 100 measures accompanied by the author's comment on the characteristics (reliability, validity, etc) of the scale.

In a book which attempts to outline the available choices in an unbiased fashion one might expect to be left with yet another wealth of information and little clear guidance. But not so. In chapter 12, the author lays out very clearly his own choice of measures in the specific circumstances of his two units (an acute rehabilitation centre, the other a young disabled unit), always with his eye on economy and relevance. The book will be invaluable for anyone involved in service provision, audit, evaluation, research, or planning future services for patients with neurological disability.

LYNNE TURNER-STOKES

In the 1970s audit was a term that was used rarely in medical parlance in the United Kingdom. In 1980, however, the BMJ brought audit to the attention of many in the medical profession by publishing a series of five introductory articles by Charles Shaw. Drawing mainly on his own experience and knowledge of quality assurance in the United States, Shaw summarised the key principles of audit and, incredibly, in two short papers was able to document the growing activity in hospitals and general practice in Britain. His paper on the acceptability of audit was written against a general background of decided lack of enthusiasm and suspicion of audit among doctors.

When writing "Looking forward to audit", Shaw probably did not realise that he would have to wait almost 10 years before the BMJ would publish another major study on audit. In the 1980s there were isolated pockets of activity among several groups — for example, the Royal College of Radiologists' multi-centre audits of the use of routine diagnostic procedures, the Lothian surgical audit of mortality and complications after surgery, the Royal College of General Practitioners' practice activity analysis, and the Confidential Enquiry into Maternal Deaths. Much good work was carried out, methods were explored, and a small cadre of individuals emerged at the dos and don'ts of audit, while publishing sporadically in the general and specialist medical journals.

After publication of the government's white paper Working for Patients in 1989, and following a request by the BMJ to respond to the fervour by including a special section on medical audit, In this section was published, dealing with many aspects of the audit field. Some of Shaw's early papers, are now brought together in Audit in Action. In 30 chapters, surgeons, physicians, specialists in public health medicine, audit officers, sociologists, and others, mainly from the United Kingdom, provide a rich insight into audit.

An appropriate organisational framework is often the key to success in audit, and this is addressed in an early section of the book. What is the role of regional specialty subcommittees? How should an individual clinician get started? What should audit officers do? In the following chapters on "Writing psychiatrists" and "Validity of methodology" issues are addressed — for example, techniques of reviewing medical records and surveying patient satisfaction. Here the book emphasises two important points. First, we are again faced with the need to case all audit. This is made explicit in Chapter 3, "Audit in general practice", an emphasis of audit from simply collecting data to making improvements in the quality of care. Clinicians wishing to do this would be advised to concentrate on the theory chapter on criterion based audit and use Bhopal and Thomson's form, described in a later chapter, as a means of educating themselves about audit when reading papers.

The final two chapters on total quality management, by Berwick, Enthoven, and Bunker from the United States, take us forward from the narrow confines of medical audit the audit industry that striving for improved quality, not just maintaining the status quo, should pervade every aspect of the organisation and be an ideal that is incorporated into every everyday decision. If this is philosophy is not quite with us in the NHS but Audit in Action, as well as providing some useful insights into audit, may help to move us in that direction.

FG R POWKES
Director, Wolfson Unit for Prevention of Peripheral Vascular Diseases, University of Edinburgh

Hugh Koch's excellent book goes much further than the usual basic text on quality, which is often "soft" in its approach and leaves people wondering: "That's all very well, but . . . ." It comes much more from his consultancy work and so is grounded in practice and refreshingly aware of all the connections between total quality management
