Quality and Safety in Health Care: a time of transition

F Moss, P Barach

QHC becomes QSHC

This issue of QHC marks its 10th anniversary—and the start of significant changes to the journal. QHC has become QSHC—Quality and Safety in Health Care. Safety is not a new topic for this journal. In the past we have included many papers relevant to risk management and the safety of health care. By adding “safety” to the title we acknowledge the growing realisation that health care systems too often harm the people who depend on them.

Finding ways to limit and stop the unnecessary and preventable discomfort, disability, and death directly attributable to the system of health care is a matter of urgent concern. Regular examples of such harm appear frequently in the world’s newspapers.1,2 In this issue Millenson3 charts the news media’s influence on exposing the extent of the damage caused by health care and the importance of telling the truth to the public. Past tragedies cannot be reversed. We owe it to those who have been harmed and to future patients to work to ensure that patients of all data about their care is the right policy. We owe it to those who have been harmed and to future patients to work to ensure that patients of all data about their care is the right policy.

Our change in title is an explicit signal that and encourage more feedback from our readers. We want to exploit the enormous capacity and flexibility provided by online access by offering background material on quality and safety of care. Electronic submission and peer review of manuscripts, online publication, and links to other sources of information are just a start. In the future our website may include online publication ahead of print, online only publication, posting detailed datasets, guidelines, case studies that include quality improvement reports and near miss and adverse events, and pictures and video clips. For now we welcome readers’ feedback and comments and hope that you will continue to send us papers on all aspects of quality and safety of health care (www.qualityhealthcare.com)

Shame is the “elephant in the room”—something so big and disturbing that we don’t even see it, despite the fact that we keep bumping into it. It is hoped that open discussion of safety issues in QSHC will remove some of the shame relating to them.

In the 1960s the results of a large randomised controlled study by the University Group Diabetes Program (UGDP) indicated that the use of tolbutamide, virtually the only blood sugar lowering agent available at the time in pill form, was associated with a significant increase in mortality rate in patients who developed myocardial infarctions. The obvious response on the part of the medical profession should have been gratitude: here was an important way to improve the safety of clinical practice. But the response was, in fact, quite different: doubt, outrage, even legal proceedings against the investigators; the controversy went on for years. Why?

An important clue to the origins of this curious anomaly surfaced at the annual meeting of the American Diabetes Association soon after the UDGP study findings were published. During the discussion a practitioner stood up and said he simply could not, and would not, accept the findings, because admitting to his patients that he had been using an unsafe treatment would shame him in their eyes. Other examples of such reactions to improvement efforts are not hard to find. Indeed, it is arguable that shame is the universal “dark side” of improvement. After all, improvement means that, however good your performance has been, it is not as good as it could be. As such, the experience of shame helps to explain why improvement—which ought to be a “no-brainer”—is generally such a slow and difficult process.

"it is arguable that shame is the universal ‘dark side’ of improvement"

What is it about shame that makes it so hard to deal with? Shame, along with embarrassment and guilt, is one of the self-conscious “moral emotions”—emotions that motivate moral behaviour. Current thinking suggests that shame is so devastating because it goes right to the core of a person’s identity, making them feel exposed, inferior, degraded as a person; although “moral” in quality, shame is also likely to be experienced in “non-moral” situations—for example, failure in performance is very much dependent on what other people think; it leads to avoidance, to silence. In these respects shame differs from guilt, which is largely concerned with a particular act or behaviour, is less damaging to someone’s overall sense of self-worth than shame, and motivates people to restitution, confession, and apology. The enormous positive power of shame is apparent in the adoption of shaming by many human rights organisations as their principal lever for social change; on the flip side lies the obvious social corrosiveness of “shameless” behaviour.

Despite its potential importance in medical life, shame has received little attention in the literature on quality improvement—indeed, in the medical literature generally. A search on the term “shame” in November 2001 yielded only 947 references, a tiny fraction of the roughly seven million articles indexed in Medline. In a sense, shame is the “elephant in the room”: something so big and disturbing that we don’t even see it, despite the fact that we keep bumping into it.

An important exception to this medical “shame blindness” is a paper published in 1987 by the psychiatrist Aaron Lazar which reminded us that patients commonly see their diseases as defects, inadequacies, or shortcomings, and that visits to doctors’ surgeries and hospitals involve potentially humiliating physical and psychological exposure. Patients respond to medical shame or the fear of it by avoiding the healthcare system, withholding information, complaining, and suing. Doctors too can feel shamed in medical encounters, which Lazar suggests provokes counterhumiliation and contributes to dissatisfaction with clinical practice. Indeed, much of the extreme distress of doctors who are sued for malpractice appears to be attributable to the shame of being sued rather than to the financial losses involved. As a related issue, who can doubt that the real agenda in the controversy currently raging over mandatory reporting of medical errors is the fear of being shamed?

Doctors may, in fact, be particularly vulnerable to shame, since they are self-selected for perfectionism when they choose to enter the profession. Moreover, the use of shaming as punishment for the shortcomings of medical students, particularly during their clinical years, and for “moral errors” committed by registrars, such as lack of sufficient dedication, hard work, and a proper reverence for role obligations, very likely contributes further to the extreme sensitivity of doctors to shaming.

What are some of the lessons here for those working to improve the quality and safety of medical care? The first is the importance of recognising that there actually is a problem: that shame is a powerful force in slowing or preventing improvement; that unless and until shame is confronted and dealt with, progress in improvement will be slow. The second is the recognition that shame is a fundamental human emotion and is not about to go away, no matter how successful we are at handling it. Once these basic ideas are firmly rooted, the work of mitigating and managing shame can really flourish.

This work has, of course, been under way for some time. The move away from “cutting off the tail of the performance curve”—that is, getting rid of “bad apples”—and towards “shifting the whole curve” as the basic strategy in quality improvement, and the recognition that medical error results as much from malfunctioning systems as from incompetent practitioners, can be seen as important developments in this regard. These new ways of reframing the issues of improvement and safety have helped to minimise challenges to the integrity of healthcare workers and support the transformation of medicine from a “culture of blame” to a “culture of safety.”

But quality improvement has another powerful tool for managing shame. Bringing issues of quality and safety out of the shadows can, by itself, remove some of the sting associated with improvement. After all, how shameful can these issues be if they are being widely shared and openly discussed (witness the recent article in *Trustee* magazine)? Here is where reports by public bodies come in, and where a journal like *Quality and Safety in Health Care*—with its new title, increased focus on safety as well as quality, and the BMJ Publishing Group’s co-ownership of the title with IHI—can make a huge difference. More specifically, such a journal supports three major elements—autonomy, mastery, and connectedness—that motivate people to learn and improve, bolstering their competence and their sense of self-worth.
and thus serving as antidotes to shame.\textsuperscript{31}

“Bringing issues of quality and safety out of the shadows can remove some of the sting associated with improvement”\textsuperscript{32}

The autonomy under consideration here is not the ugly variety of blind self-sufficiency that isolates and divides; rather, it is the sense that the learning and the improvement belong to the learner, rather than being imposed from outside. Getting the information on improvement that they need, when they need it, and out of their own dedicated journal certainly supports the readers’ sense of autonomy. High quality, theoretically grounded, practical journal content can certainly contribute to the mastery of the readers—knowing something, knowing how to do it, and how to do it well. And knowing as they read their journal that hundreds or thousands of like-minded people are reading the same material at roughly the same time certainly creates a sense of connectedness—instant community, if you will.

May Quality and Safety in Health Care live long and prosper, and may it help to capture and tame the elephant in the room. It would be a real shame if it didn’t.

Patient safety

The end of the beginning: the strategic approach to patient safety research

G S Meyer, J M Eisenberg

Research into patient safety has undergone a period of rapid acceleration since the decision of the US AHRQ to make a specific commitment to fund research into systems for improving patient safety

Patient safety is not a new issue and has been the subject of research internationally for decades. Funding for patient safety in the US has been around for some time and, in fact, work cited in the Institute of Medicine (IOM)’s landmark report\textsuperscript{1} was funded by the Agency for Healthcare Research and Quality (AHRQ). Supported research has investigated preventable adverse drug events,\textsuperscript{2} the role of systems failures in the aetiology of medical errors,\textsuperscript{3} and the effects of the healthcare workforce on safety.\textsuperscript{4} Other funding in Australia and the UK has advanced our knowledge of patient safety considerably.

The funding of these important studies, however, was not based on any strategic commitment to addressing the patient safety challenge but, instead, the approach of research funders to patient safety had been an opportunistic one. The agencies solicited bright patient safety researchers employing sound methodology to address compelling issues. Funding was awarded on the basis of the ability to compete successfully against a wide range of healthcare issues. As a result, the number of researchers involved, the armamentarium of methodologies, and the scope of the research has been relatively limited.

BACKGROUND

In 1999 the US AHRQ made the decision to take a different, more strategic approach to patient safety research. The Agency’s fiscal year 2000 budget included a specific commitment to fund research in patient safety through a modest 8.2 million investment in research on systems related best practices in improving patient safety.\textsuperscript{5} It was hoped that this initial foray into funding patient safety research would slowly evolve into a sustained initiative which would gradually grow in terms of both importance and investment.

The IOM report,\textsuperscript{6} however, dramatically changed the deliberate but slow transition to a more strategic approach in funding patient research in the US. The report highlighted the urgent need to develop an evidentiary base for safety improvement through research. In response to the IOM report, the President asked the federal government’s Quality Interagency Coordinating Task Force (QuIC) to draft a comprehensive plan to address the issues of medical errors and patient safety.\textsuperscript{7} Both the IOM and QuIC reports called for a substantial targeted investment in patient safety research which became a reality with the appropriation of 50 million for patient safety research in AHRQ’s fiscal year 2001 budget.

“Be careful what you wish for”

The myriad of challenges in affecting the strategic transformation of patient safety research have, at times, suggested the adage of “be careful what you wish for . . .”. Because patient safety research was not a new field, agenda setting and the mechanisms to support research had to be cognisant of its history. Existing literature from the safety field, for example, demonstrated the value of a multidisciplinary approach to patient safety research demanding novel tactics to promote multidisciplinary teams of researchers. The relative paucity of funding had led to a situation where there were relatively few established researchers in
Editorials

WHERE ARE WE TODAY AND WHERE MUST WE GO?

The patient safety research community has much to be proud of. There is a previously unimagined support for the field, exciting new research projects and teams, international interest and, now, a new journal dedicated to reporting these exciting findings and programmes. But significant responsibilities have come with these opportunities. The momentum for patient safety research can only be maintained if the promises made are indeed kept. The research community must not only produce an enhanced evidentiary base for safety improvement, but must also ensure that these results are translated into practice.

The transformation to a strategic approach to patient safety research has undergone a period of rapid acceleration. We have reached the end of the beginning. Funding agencies around the world are looking at the US strategic approach to funding patient safety. It is rare for a research paradigm to evolve in real time, and it is incumbent upon the patient safety research community to ensure that this transformation is sustained and not ephemeral. Continued support for patient safety research demands a return on investment. Producing great research is not enough, we must improve safety. We owe it to our patients and the public.

New QSHC online submission and review system: important message for all authors and reviewers

F Moss

New online submission and review system for QSHC

From January 2002 QSHC will be linked into a new online submission and reviewing system. Developed by Highwire Press (CA, USA), Bench>Press® is a fully integrated electronic system which utilises the web to allow rapid and efficient submission of manuscripts. It also enables the peer review process to be conducted entirely online. QSHC is one of the first in the BMJ Publishing Group to go on line in this way; the aim—apart from saving trees—is to speed up the frequently frustrating progress of papers from submission to publication.

Authors can submit manuscripts in any standard word processing software. Standard graphic formats acceptable include .jpg, tiff, .gif, and eps. Text and graphic files are automatically converted to PDF for ease of distribution and reviewing purposes. Authors will be asked to approve their submission before it formally enters the reviewing process; once that has been done, papers will be sent to the editor and to reviewers via the web. All transactions are secure.

You can access the system by clicking on “Submit Your Manuscript Here” on the QSHC home page (http://www.qualityhealthcare.com) or you can access Bench>Press directly at http://submit-qhc.bmjournals.com.

We are very excited with this new development and want to encourage authors and reviewers to use the online system where possible. It really is simple to use and should be a big improvement on the current peer review process. Full instructions can be found on Bench>Press http://submit-qhc.bmjournals.com and QSHC online at http://qhc.bmjournals.com. Please contact Natalie Davies, Project Manager, ndavies@bmjgroup.com for further information.
