Patients’ experiences and satisfaction with health care: results of a questionnaire study of specific aspects of care

C Jenkinson, A Coulter, S Bruster, N Richards, T Chandola

Objective: To determine what aspects of healthcare provision are most likely to influence satisfaction with care and willingness to recommend hospital services to others and, secondly, to explore the extent to which satisfaction is a meaningful indicator of patient experience of healthcare services.

Design: Postal survey of a sample of patients who underwent a period of inpatient care. Patients were asked to evaluate their overall experience of this episode of care and to complete the Picker Inpatient Survey questionnaire on specific aspects of their care.

Sample: Patients aged 18 and over presenting at five hospitals within one NHS trust in Scotland.

Method: 3592 questionnaires were mailed to patients’ homes within 1 month of discharge from hospital during a 12 month period. Two reminders were sent to non-responders; 2249 (65%) questionnaires were returned.

Results: Almost 90% of respondents indicated that they were satisfied with their period of inpatient care. Age and overall self-assessed health were only weakly associated with satisfaction. A stepwise linear regression indicated that the major determinants of patient satisfaction were physical comfort, emotional support, and respect for patient preferences. However, many patients who reported their satisfaction with the care they received also indicated problems with their inpatient care as measured on the Picker Inpatient Survey; 55% of respondents who rated their inpatient episode as “excellent” indicated problems on 10% of the issues measured on the Picker questionnaire.

Discussion: The evidence suggests that patient satisfaction scores present a limited and optimistic picture. Detailed questions about specific aspects of patients’ experiences are likely to be more useful for monitoring the performance of various hospital departments and wards and could point to ways in which delivery of health care could be improved.

Evaluation of healthcare provision is essential in the ongoing assessment and consequent quality improvement of medical services. Traditionally, assessments have ignored the reports of patients in preference to technical and physiological reports of outcome. More recently, however, healthcare systems have sought to achieve a balance in services that offer not only clinically effective and evidence based care, but which are also judged by patients as acceptable and beneficial.1 Health care which improves health only in some limited technical sense, but does not improve the quality or length of life, is not likely to be viewed as beneficial by patients.2 Interest has therefore grown not only in the assessment of treatment interventions by patients, but in the systematic evaluation of the delivery of that care.3 Most significantly, attempts have been made to determine the features of patient care that are likely to influence patient satisfaction.

Patient satisfaction is not a clearly defined concept, although most typically it appears to represent attitudes to care or aspects of care.4 While numerous questionnaires have been developed which ask people to rate aspects of care, such an approach has limitations. Attitudes to services do not tell us very much about the nature of those services. Surveys of patient satisfaction tend to elicit very positive ratings which are not sensitive to specific problems in the quality of care delivery. It has been argued that questionnaires should attempt to measure patients’ experiences of their care, and then determine how such experiences are related to satisfaction.5 Patient satisfaction questionnaires have been criticised for failing to discriminate effectively between good and bad practice as they rarely ask patients about the value to them of their treatment.6 The Picker Institute has developed instruments which seek detailed information on patients’ experiences of health care.7 These questionnaires are focused on specific dimensions of patient care—including information and communication, coordination of care, respect of patient preferences, involvement of family and friends, and continuity and transition. The questionnaires do not ask if patients are satisfied with these aspects of care but, instead, whether certain processes and events occurred during the course of a specific episode of care. Not only do the Picker instruments avoid asking if patients were satisfied with their care, but they address issues of particular salience to patients. The content of the measures is built upon qualitative in depth interviews with patients and focus groups. The questions included in the Picker survey reported here have been chosen to reflect concerns of patients.

The purpose of this study was (1) to determine what factors are most likely to influence satisfaction with care and willingness to recommend hospital services to others and (2) to explore the extent to which satisfaction is a meaningful indicator of patients’ experience of healthcare services.

METHODS

Picker survey of patient experiences questionnaire

The conceptual basis and design of Picker questionnaires has been described elsewhere.7 The development of the initial instrument was undertaken at the Picker Institute in Boston, USA. Questions to be included in the instrument were devised on the basis of a literature review and in depth interviews and focus groups with patients to determine their priorities, and these were reviewed and put in questionnaire format by an expert advisory group. This produced a pilot version of the instrument which was tested using cognitive interviews with patients, and then redrafted and piloted. This instrument has
Standing of the questions.

Measure and, while doing so, to comment on their under-

tive interviews in which they were asked to complete the

This adaptation which was then assessed by patients in cogni-

healthcare researchers, managers, and clinicians undertook

that the wording of questions in the UK version was semanti-

modified by removing questions on payment and ensuring

bills was not raised.

expressed in the USA, except that the issue of paying medical

using focus groups, reported very similar concerns to those

context was evaluated before its use. Patients, interviewed

reported here. The appropriateness of the measure in the UK

subsequently been used extensively in the USA since 1987,

and formed the basis of the instrument used in the survey

reported. The appropriateness of the measure in the UK
context was evaluated before its use. Patients, interviewed

The questionnaire comprises 40 items which measure seven

core dimensions: information and education; coordination of
care; physical comfort; emotional support; respect for patient

preferences; involvement of family/friends; and continuity of
care. Each item is coded for statistical analysis as a

dichotomous “problem score”, indicating either the presence

or absence of a problem. A problem is defined as an aspect of

health care that could, in the eyes of the patient, be improved

upon. An example of questions in the instrument and how

they are coded as problem scores appears in fig 1. Each domain

is then scored from 0 (no reported problems) to 100 (all items
coded as a problem).

A further two items were also included in the questionnaire

booklet: the first (referred to as the “satisfaction” item) asked

patients to rate their overall evaluation of care on a 5 point

scale (with response categories of poor, fair, good, very good,

and excellent). The second (referred to as the “recommen-
dation” item) asked patients if they would recommend the

hospital to others on a 3 point scale (with possible response
categories of yes, yes probably, and no).

Study design

The data were collected by a commissioned postal survey of

patients undertaken in 1999. Questionnaires were mailed

within 1 month of discharge to the homes of patients aged 18

and over. Nine provider units were surveyed, covering five spe-
cialties in five hospitals in one NHS trust in Scotland. The

patients were randomly selected from the Hospital Infor-

mation System stratified by provider unit, age, and sex.

The sample size was based on previous experience of Picker

survey instruments which suggested that approximately 300

respondents per provider unit would lead to narrow 95% con-
fidence intervals around individual item scores, assuming an

average problem rate per item of 25%. Assuming a response

rate of 60–65%, a sample size of 450 questionnaires per

provider unit would produce more than sufficient data for

analysis, leading to a planned total of 4050 questionnaires

being mailed. However, the number of elderly patients admit-
ted and discharged during the period of the study was small

and hence the total number of questionnaires mailed was

slightly less at 3592. Two reminders were sent to non-

responders; 2249 (65%) questionnaires were returned.

Statistical analysis

Residuals were checked for normality to ensure that

regression analysis could be performed on the data. Normality

was checked by graphing the normal probability plot which
did not detect any significant departure from normality. The

regression analysis was undertaken to determine which of the

seven dimensions of the Picker questionnaire (together with

age, self-reported health, and sex) appeared to be significantly

associated with patient satisfaction as the dependent variable.

To determine whether assessment of global satisfaction

provides an optimistic picture of healthcare experiences and

consequently underestimates the number of problems en-
countered, the number of responses indicating problems on

Figure 1 Example items of those included in the questionnaire. Black boxes indicate responses coded as a “problem”.

Were you given enough privacy when discussing your treatment?
1  ☐ Yes
2  ☐ No

Did doctors talk in front of you as if you weren’t there?
1  ☐ Yes, often
2  ☐ Yes, sometimes
3  ☐ No
4  ☐ I had no need to talk to doctor

Did you want to be more involved in decisions made about your care?
1  ☐ Yes, often
2  ☐ Yes, sometimes
3  ☐ No

Sometimes in hospital one doctor or nurse will say one thing and another will say something quite different. Did this happen to you?
1  ☐ Yes, often
2  ☐ Yes, sometimes
3  ☐ No
the Picker questionnaire was broken down by overall satisfaction ratings. All correlations reported are Spearman coefficients.

RESULTS

The data set contained 2249 respondents, 1186 (52.7%) women and 1029 (45.8%) men. Thirty-four (1.5%) respondents did not answer the question relating to sex. The mean (SD) age was 60.9 (18.0) years (range 18–98). 920 (40.9%) were planned admissions and 1116 (49.6%) were emergency admissions. The specialties under which patients were admitted are shown in Table 1. The mean age of patients was 45.8 (14.5) years (range 18–98) and the mean age of patients who would recommend the hospital was 49.8 (14.3) years (range 18–98). The Picker questionnaire was broken down by overall satisfaction ratings. All correlations reported are Spearman coefficients.

Because of differences in direction in the coding of variables, a negative correlation indicates a positive relationship. Table 2 shows correlation coefficients of the dimensions of the Picker survey and satisfaction. Table 5 shows both standardised and unstandardised coefficients and levels of significance for age, self-reported health status, and sex (as a dummy variable), together with the seven Picker domains as independent variables and the 5 point satisfaction item as the dependent variable in a linear regression. An adjusted $R^2 = 0.48$ was achieved. The results suggest that the major determinants of patient satisfaction are physical comfort, emotional support, and respect for patient preferences ($p<0.0001$). Age ($p<0.02$), involvement of family and friends ($p<0.001$), and continuity of care ($p<0.001$) also contributed to the model.

Another potential source of satisfaction is the number of items on which people report problems, so the total number of items completed by each patient (range 0–40) was calculated. Patient overall satisfaction was highly correlated with the number of items completed (Spearman $\rho=0.65$, $p<0.001$; $n=2182$). The association of level of satisfaction with the number of items completed (Spearman $\rho=0.65$, $p<0.001$; $n=2182$) was highly correlated. However, the levels of correlation were low. Modest but significant correlations were found between satisfaction and overall assessment of health status (Spearman $\rho=0.21$, $p<0.001$, $n=955$) and age (Spearman $\rho=0.10$, $p<0.002$, $n=941$). Higher correlations were found between dimensions of the Picker survey and satisfaction. Table 5 shows both standardised and unstandardised coefficients and levels of significance for age, self-reported health status, and sex (as a dummy variable), together with the seven Picker domains as independent variables and the 5 point satisfaction item as the dependent variable in a linear regression. An adjusted $R^2 = 0.48$ was achieved. Evidence suggests that patients generally indicate that they are satisfied with care. The results reported here similarly find high levels of reported satisfaction. Furthermore, satisfaction is very highly associated with willingness to recommend to others the hospital in which they received treatment. However, many respondents who indicated that they were satisfied with their healthcare also indicated problems in aspects of their inpatient episode. Indeed, on the related dimension of willingness to recommend the hospital to others, problems were indicated on all dimensions of the Picker questionnaire for those patients who indicated they would be happy to do so. This seems to suggest that satisfaction with patient care and willingness to recommend a medical facility does not imply that all aspects of that care were successfully delivered. This confirms the results from other industries, such as civil aviation, where satisfaction scores may be high but customer complaints about specific aspects of the service continue.

The evidence presented here would suggest that patient satisfaction scores, and the related issues of willingness to recommend a hospital to others, present a limited and optimistic picture. Detailed questions about specific aspects of patients’ experiences are more likely to be useful for monitoring the performance of various hospital departments and wards and could point to ways in which healthcare delivery could be improved. Data such as these presented here indicate what areas of healthcare provision may be in need of change or improvement. Analysis of data at the level of the actual questions can help to pinpoint the exact issues needing to be addressed. If satisfaction with the process of care is truly one of the goals of the health professions, then the way in which care is delivered must be evaluated through the eyes of the patient. It has only been relatively recently that health service providers have come to believe that patients can provide reliable judgements of their experiences of health and health care. The evidence provided here would suggest that it can be done in a way that provides meaningful information, which in turn can be used to improve service delivery.

Table 7 Number (%) of problems indicated on the Picker survey broken down by satisfaction with care overall.
Patients' experiences and satisfaction with health care

Key messages

- Overall satisfaction with care is influenced by the number of areas in which patients experience what they perceive to be less than optimal care.
- Overall satisfaction provides an overoptimistic evaluation of patients' experiences of health care.
- Measuring experiences of health care, rather than satisfaction, provides a more meaningful indication of the quality of care received.
- The Picker Inpatient Survey, developed from interviews with patients themselves, can provide information on areas that may need improvement in the eyes of patients.

What this paper adds to the topic

The results are in agreement with previous patient satisfaction research but go further in indicating that more meaningful information is gained when patients are asked to report on specific aspects of their experience of care.
