LETTERS TO THE EDITOR

Culture of safety

Congratulations to Singer et al for the comprehensive survey of safety culture performed in 15 hospitals. The overall response rate of only 47.4% was largely due to the poor response by physicians (33%). Efforts need to be made to increase the response rate to achieve a more reliable result. Most of the participants in the survey responded in ways which indicated a culture of safety. However, it would be interesting to determine the safety culture of the hospitals which do not participate in the “hospitals participating in the California Patient Safety Consortium” group. It is noted that higher responses are attributable to shorter survey questions. People are generally not interested if they have to go through large formats. Clinicians, as expected, were more critical about the patient care safety and thus scored more “problematic responses”. The survey sample noted that a total of 6312 eligible individuals participated. That figure is actually 6332 individuals (initial mailing list of 6909 minus 347 duplicates minus 227 undeliverable = 6332). The high percentage of non-respondents (an overall figure of 56%) may possibly still lead to non-response bias. A survey of the non-responders would be interesting.

Senior managers gave fewer problematic responses than frontline workers. Generally speaking, all senior managers will want to give a high opinion of their own organization/institution. In addition, they may not have been briefed about the patient care problems.

Using the High Reliability Organization (HRO) standard cut off point of 10% problematic attitudes, the results of an overall problematic response of 13% is worrying. Generally it can be assumed that we still need to improve and to internalize the culture of safety in healthcare settings among all levels of healthcare workers. A culture of safety should be instilled into all healthcare workers from their undergraduate student days if it is to be internalized within ourselves. Stevens emphasizes that “improving health and safety out of the shadows can remove the fear of blame”. What they have done is to use a blunt survey instrument to assess the opinions of individual members of staff to a series of statements about safety. The responses represent the most superficial evaluation of the “climate” of the organisations in which they work. These opinions are likely to be influenced by a wide range of factors that have little to do with the organisation’s culture. Furthermore, the relationship between these opinions and the shared values that underlie them is largely unknown.

If we really want to understand the safety culture of an organisation, we need to use more sophisticated approaches. These should draw on a wide range of methods—participant observation, in-depth and semi-structured interviews and focus groups, together with attitudinal surveys and the use of new and established culture measurement tools. Developmental or action research approaches might provide additional insights into the complexity of the organisations. This presents a significant challenge to health service researchers. Singer and colleagues have made a start, but there is a long way to go before we know how—or, indeed, whether—it is possible to change the safety culture of our hospitals and primary care centres.

We welcome Singer and colleague’s contribution to developing the concept of a safety culture. Policy makers, managers, and clinicians are slowly realising that patient safety will not be improved solely by counting adverse events or by introducing technical fixes. However, when these initiatives are evaluated, the results will probably show a marginal impact on patient safety and one that is likely to be poorly sustained. In order to maximise their impact we need to understand the shared attitudes, beliefs, values, and assumptions that underlie how people perceive and act upon safety issues within their organisations. This is what is commonly called the “safety culture” of an organisation.

The problem with the approach adopted in this paper is that it fails to get to the heart of the hospital’s culture. What they have done is to use a blunt survey instrument to assess the opinions of individual members of staff to a series of statements about safety. The responses represent the most superficial evaluation of the “climate” of the organisations in which they work. These opinions are likely to be influenced by a wide range of factors that have little to do with the organisation’s culture. Furthermore, the relationship between these opinions and the shared values that underlie them is largely unknown.

If we really want to understand the safety culture of an organisation, we need to use more sophisticated approaches. These should draw on a wide range of methods—participant observation, in-depth and semi-structured interviews and focus groups, together with attitudinal surveys and the use of new and established culture measurement tools. Developmental or action research approaches might provide additional insights into the complexity of the organisations. This presents a significant challenge to health service researchers. Singer and colleagues have made a start, but there is a long way to go before we know how—or, indeed, whether—it is possible to change the safety culture of our hospitals and primary care centres.

BOOK REVIEWS

Quantifying Quality in Primary Care

It is always helpful to have a checklist for any task, whether it is for simply preparing to go on an overseas trip or something as complex as ensuring a high quality service for patients in primary care. It is even better if someone as experienced as Peter Graves has compiled one for you, which can be the basis of your own tailor-made solution.

Clinical governance is at the heart of this book, but many sources are used to inform its content such as NHS (GMS) regulations, Health and Safety at Work laws, and the GMC’s views on Good Medical Practice. The main areas that are addressed are "The Patient’s Experience", “Patient Management and Treatment”, and “Practice Management”, and if all three are right then the aim of good patient care and outcomes will be achieved.

The charts and scoring system are consistent and very sensible. The layout is clear and the questions are realistic, with a range of scores possible that will help practices understand their current position and enable them to plan for improvement.

Few will take the whole content on board but, as a basis for assessing even just a few areas where weakness is perceived, the order and common sense brought to the process will be rewarding.

Getting Health Economics into Practice

It was with a somewhat heavy heart that I accepted the challenge to write a review of an economics book. Although I knew the editor wrote well, a book on economics was not at the top of my reading list. It would do me some good, I thought. In the end it wasn’t a challenge—I read the book in two weeks, enjoying the puns, the well written text, and—yes—it did me good. But unlike many self-betterment schemes, it was painless.

What stood out were the clear aims at the start of the book and the introductions to each section and to most chapters. Sometimes this
An A–Z of Management for Healthcare Professionals

An A–Z of Management for Healthcare Professionals

T Wilson
Strategy Unit, Department of Health, London, UK; tim.wilson@doh.gsi.gov.uk

Dr Lilley’s “management” book is an intuitive guide to what managers can achieve. His approach is simple and direct, making it easy to understand.

One of the most useful features of this book is the alphabetical order of the topics. This makes it easy to find specific information quickly and efficiently.

In addition to the alphabetical order, the book includes additional sections on topics such as leadership, motivation, communication, and ethics. These sections provide valuable insights into the challenges faced by managers in the healthcare industry.

Overall, this book provides a comprehensive guide to management in healthcare. It is an excellent resource for those looking to improve their management skills in this field.

Using the Internet in Healthcare. 2nd Edition

The internet is an integral part of our healthcare system. This book will not replace the IT support staff or the hands-on computing courses, but it will inform clinicians and administrators who want to gain confidence about using internet technologies in daily practice.

Stuart Tyrrell seeks to educate us about the internet. He provides overviews about what the internet is and how internet technologies such as intranets, e-mail, and the world wide web work using clear language and explanations. He demystifies web page design and addresses current issues such as the security and quality of online health information. Mike Ingham also authors a chapter outlining the role of the internet as an organisational communications medium using an NHS case study.

The chapter entitled “Searching and Sifting” provides an excellent introduction for beginners searching the world wide web for health and non-health related information. Like most of this book, it is easy to read and will allay the fears of the most ardent technophobes. However, it lacks a discussion of health portals and will not meet the needs of clinicians or students wishing to undertake systematic literature reviews.

Although this is a valuable addition to the Harnessing Health Information Series, it is limited by its technological viewpoint. There is sparse discussion of the applications of internet technologies to improve healthcare delivery and services. For example, the concepts of e-commerce and SMS messaging in health care are introduced without reference to some pharmacies or GPs using text messaging to improve medication compliance.

There is little mention of telemedicine, online support groups, e-book reading, e-health promotion, e-prescribing or online clinical trials and research. Thus, it may fail to inspire those clinicians and administrators seeking ways to improve access to or efficiency of healthcare delivery in their own practices.

Stuart Tyrrell provides a short but limited discussion about the future implications of e-health technologies for the NHS, consumers, and healthcare providers. He mentions the potential e-health issues such as the globalisation of health care but does not elaborate on the potential effects on policies, costs, and outcomes. There is also no mention of guidelines for the exchange of clinical information between clinicians and consumers or the opportunity for shared clinical decision making and outcome monitoring.

In summary, if this book was a red wine I would describe it as “medium colour; well balanced with integrated fruit and oak; good weight and structure; overall soft and approachable; drink now”. However, those readers seeking a more complex vintage will have to wait for the 3rd edition.

In the paper entitled “A national survey of audit activity across the primary-secondary care interface” by M Eccles, M Deverill, E McColl, and H Richardson which was published in Quality in Health Care, 1996; 5:193–200, the number of audits in column 1 of table 3 headed “Audit complete” should be 117, not 177.
